Abstract

In this paper, for finding a zero of a monotone variational inclusion in Hilbert spaces, we introduce new modifications of the Halpern forward-backward splitting methods, strong convergence of which is proved under new condition on the resolvent parameter. We show that these methods are particular cases of two new methods, introduced for solving a monotone variational inequality problem over the set of zeros of the inclusion. Numerical experiments are given for illustration and comparison.

1. Introduction The problem, studied in this paper, is to find a zero \( p \) of the following variational inclusion

\[
0 \in Tp, \ T = A + B, \tag{1.1}
\]

where \( A \) and \( B \) are maximal monotone and \( A \) is single valued in a real Hilbert space \( H \) with inner product and norm denoted, respectively, by \( \langle \cdot, \cdot \rangle \) and \( \| \cdot \| \). Throughout this paper, we assume that \( \Gamma := (A + B)^{-1}0 \neq \emptyset \).

Key words: Nonexpansive operator · fixed point · variational inequality · monotone variational inclusion.

2010 AMS Mathematics Classification: 47J05, 47H09, 49J30.

Note that there are two possibilities here: either $T$ is also maximal monotone or $T$ is not maximal monotone. A fundamental algorithm for finding a zero for a maximal monotone operator $T$ in $H$ is the proximal point algorithm: $x_1 \in H$ and either
\begin{align}
x^{k+1} = J^T_k x^k + e^k, \quad k \geq 1, \tag{1.2}
\end{align}
or
\begin{align}
x^{k+1} = J^T_k (x^k + e^k), \quad k \geq 1, \tag{1.3}
\end{align}
where $J^T_k = (I + r_k T)^{-1}$, $I$ is the identity mapping in $H$, $r_k > 0$ is called a resolvent parameter and $e^k$ is an error vector. This algorithm was firstly introduced by Martinet [23]. In [26], Rockafellar proved weak convergence of (1.2) or (1.3) to a point in $\Gamma$. In [15], G"{u}ler showed that, in general, it converges weakly in infinite dimensional Hilbert spaces. In order to obtain a strongly convergent sequence from the proximal point algorithm, several modifications of (1.2) or (1.3) has been proposed by Kakimura and Takahashi [18], Solodov and Svaiter [29], Lehdili and Moudafi [19], Xu [38], and then, they were modified and improved in [1, 2, 4, 9, 12-14, 16, 21, 22, 27, 28, 30, 32-36, 40] and references therein.

In many cases, when $T$ is not maximal monotone, even if $T$ is maximal monotone, for a fixed $r_k > 0$, $I + r_k T$ is hard to invert, but $I + r_k A$ and $I + r_k B$ are easier to invert than $I + r_k T$, one of the popular iterative methods used in this case is the forward-backward splitting method introduced by Passty [25] which defines a sequence $\{x^k\}$ by
\begin{align}
x^{k+1} = J_k (I - r_k A)x^k, \tag{1.4}
\end{align}
where $J_k = (I + r_k B)^{-1}$. Motivated by (1.4), Takahashi, Wong and Yao [31], for solving (1.1) when $A$ is an $\alpha$-inverse strongly monotone operator in $H$, introduced the Halpern-type method,
\begin{align}
x^{k+1} = t_k u + (1 - t_k) J_k (I - r_k A)x^k \tag{1.5}
\end{align}
where $u$ is a fixed point in $H$, and proved that the sequence $\{x^k\}$, generated by (1.5), as $k \to \infty$, converges strongly to a point $P_{\Gamma} u$, the projection of $u$ onto $\Gamma$, under the following conditions:

(t) $t_k \in (0, 1)$ for all $k \geq 1$, $\lim_{k \to \infty} t_k = 0$ and $\sum_{k=1}^{\infty} t_k = \infty$;

(t') $\sum_{k=1}^{\infty} |t_{k+1} - t_k| < \infty$; and

(r') $\{r_k\}$ satisfies
\begin{align}
0 < \varepsilon \leq r_k \leq 2\alpha, \sum_{k=1}^{\infty} |r_{k+1} - r_k| < \infty,
\end{align}

where $\varepsilon$ is some small constant. Several modified and improved methods for (1.1) were presented in [11, 17, 20, 31], strong convergence of which is guaranteed under some conditions one of which is (r'). Recently, combining (1.5) and
the contraction proximal point algorithm [34, 40] with the viscosity approximation method [24] for nonexpansive operators, an iterative method,

\[ x_{k+1}^n = t_k f(x_k) + (1 - t_k)J_k(I - r_k A)x_k \] (1.6)

where \( f \) is a contraction on \( H \), was investigated in [3], strong convergence of which is proved under the condition \( 0 < \varepsilon \leq r_k \leq \alpha \). In all the works, listed above, and references therein, it is easily to see that \( \sum_{k=1}^{\infty} r_k = \infty \). Very recently, the last condition on \( r_k \) was replaced by \((\hat{r}) r_k \in (0, \alpha) \) for all \( k \geq 1 \) and \( \sum_{k=1}^{\infty} r_k < +\infty \) for the method

\[ x_{k+1} = T_k(t_k u + (1 - t_k)x_k + e^k) \] (1.7)

and its equivalent form

\[ z_{k+1} = t_k u + (1 - t_k)T_k z_k + e^k, \] (1.8)

introduced by the authors [8], where \( T_k = T_1 T_2 \cdots T_k \) and \( T_i = J_i(I - r_i A) \) for each \( i = 1, 2, \cdots, k \). They proved strongly convergent results under conditions \((t), (\hat{r})\),

\( (e) \) either \( \sum_{k=1}^{\infty} \|e_k\| < \infty \) or \( \lim_{k \to 0} \|e_k\|/t_k = 0 \) and

\( (d) \) \( \|Ax\| \) and \( |Bx| \leq \varphi(\|x\|) \), where \( |Bx| = \inf \{|y| : y \in Bx\} \) and \( \varphi(t) \) is a non-negative and non-decreasing function for all \( t \geq 0 \).

It is easily to see that methods (1.7) and (1.8) are quite complicated, when \( k \) is sufficiently large, because the number of forward-backward operators \( T_i \) is increased via each iteration step. Moreover, the second condition on \( r_k \) in \((\hat{r})\) and condition \( (d) \) decrease the usage possibility of these methods. To overcome the drawback, in this paper, we introduce the new method

\[ x_{k+1} = T_k T_c(t'_k u + (1 - t'_k)x_k + e^k) \] (1.9)

and its equivalent form

\[ x_{k+1} = t'_k u + (1 - t'_k)T_k T_c x_k + e^k, \] (1.10)

that are simpler than (1.7) and (1.8), respectively, and two new methods,

\[ x_{k+1} = t'_k u + \beta'_k T_c x_k + \gamma'_k T_k x_k + e^k, \] (1.11)

and

\[ x_{k+1} = t'_k f(T_c x_k) + \beta'_k T_c x_k + \gamma'_k J_k x_k + e^k, \] (1.12)

with some conditions on positive parameters \( t'_k, \beta'_k \) and \( \gamma'_k \), where, as for \( T_k \), the operator \( T_c = (I + cB)^{-1}(I - cA) \) with any sufficiently small positive number
Modified forward-backward splitting methods in Hilbert spaces

c, i.e., 0 < c < α. Methods (1.9)-(1.12) contain only two forward-backward operators $T_k$ and $T_c$ at each iteration step $k$. As in [8], we will show that (1.9) with (1.10) and (1.11) with (1.12) are special cases of the methods

$$x^{k+1} = T_k T_c [(I-t_k F)x^k + e^k]$$

and

$$x^{k+1} = \beta_k (I-t_k F)T_c x^k + (1-\beta_k)T_k x^k + e^k,$$

respectively, to solve the problem of finding a point $p^* \in \Gamma$ such that

$$\langle F p^*, p^* - p \rangle \leq 0 \quad \forall p \in \Gamma,$$

where $F : H \to H$ is an $\eta$-strongly monotone and $\tilde{\gamma}$-strictly pseudocontractive operator with $\eta + \tilde{\gamma} > 1$. The last problem has been studied in [39], recently [7] in the case that $A \equiv 0$ and [8] (see also references therein). We will show that the sequence $\{x^k\}$, generated by (1.13) or (1.14), converges strongly to the point $p^*$ in (1.15), under conditions (t), (e),

(r) $c, r_k \in (0, \alpha)$ for all $k \geq 1$ and

(β) $\beta_k \in [a, b] \subset (0, 1)$ for all $k \geq 1$.

Clearly, the second requirement in $(\tilde{r})$ and condition (d) are removed for new simple methods (1.9)-(1.12).

The rest of the paper is organized as follows. In Section 2, we list some related facts, that will be used in the proof of our results. In Section 3, we prove strong convergent results for (1.13) with (1.14) and obtain their particular cases such as (1.9), (1.10), (1.11) and (1.12). A numerical example is given in Section 4 for illustration and comparison.

2. Preliminaries

The following facts will be used in the proof of our results in the next section.

**Lemma 2.1** Let $H$ be a real Hilbert space. Then, the following inequality holds

$$\|x + y\|^2 \leq \|x\|^2 + 2 \langle y, x + y \rangle, \quad \forall x, y \in H.$$ 

**Definition 2.1** Recall that an operator $T$ in a real Hilbert space $H$, satisfying the conditions $\langle Tx - Ty, x - y \rangle \geq \eta \|x - y\|^2$ and

$$\langle Tx - Ty, x - y \rangle \leq \|x - y\|^2 - \tilde{\gamma}\|(I - T)x - (I - T)y\|^2,$$

where $\eta > 0$ and $\tilde{\gamma} \in [0, 1)$ are some fixed numbers, is said to be $\eta$-strongly monotone and $\tilde{\gamma}$-strictly pseudocontractive, respectively.

**Lemma 2.2** (see, [10]) Let $H$ be a real Hilbert space and let $F : H \to H$ be an $\eta$-strongly monotone and $\tilde{\gamma}$-strictly pseudocontractive operator with $\eta + \tilde{\gamma} > 1$. Then, for any $t \in (0, 1)$, $I - tF$ is contractive with constant $1 - t \tau$ where $\tau = 1 - \sqrt{(1-\eta)/\tilde{\gamma}}$. 
Definitions 2.2 An operator $T$ from a subset $C$ of $H$ into $H$ is called:
(i) nonexpansive, if $\|Tx - Ty\| \leq \|x - y\|$ for all $x, y \in C$;
(ii) $\alpha$-inverse strongly monotone, if $\alpha\|Tx - Ty\|^2 \leq \langle Tx - Ty, x - y \rangle$ for all $x, y \in C$, where $\alpha$ is a positive real number.
We use $Fix(T) = \{x \in D(T) : Tx = x\}$ to denote the set of fixed points of any operator $T$ in $H$ where $D(T)$ is the domain of $T$.

Definitions 2.3 Let $B : H \to 2^H$ and $r > 0$.
(i) $B$ is called a maximal monotone operator if $B$ is monotone, i.e.,
$$\langle u - v, x - y \rangle \geq 0$$
for all $u \in Bx$ and $v \in By$,
and the graph of $B$ is not properly contained in the graph of any other monotone mapping;
(ii) $D(B) := \{x \in H : Bx \neq \emptyset\}$ and $R(B) = \{y \in Bx : x \in D(B)\}$ are, respectively, the domain and range of $B$;
(iii) The resolvent of $B$ with parameter $r$ is denoted and defined by $J^B_r = \left(I + rB\right)^{-1}$.
It is well known that for $r > 0$,
i) $B$ is monotone if and only if $J^B_r$ is single-valued;
ii) $B$ is maximal monotone if and only if $J^B_r$ is single-valued and $D(J^B_r) = H$.

Lemma 2.3 (see, [37]) Let $\{a_k\}$ be a sequence of nonnegative real numbers satisfying the following condition $a_{k+1} \leq (1 - b_k)a_k + b_kc_k + d_k$, where $\{b_k\}, \{c_k\}$ and $\{d_k\}$ are sequences of real numbers such that
(i) $b_k \in [0, 1]$ and $\sum_{k=1}^{\infty} b_k = \infty$;
(ii) $\limsup_{k \to \infty} c_k \leq 0$;
(iii) $\sum_{k=1}^{\infty} d_k < \infty$.
Then, $\lim_{k \to \infty} a_k = 0$.

Lemma 2.4 (see, [3]) Let $H$ be a real Hilbert space, let $B$ be a maximal monotone operator and let $A$ be an $\alpha$-inverse strongly monotone one in $H$ with $\alpha > 0$ such that $\Gamma \neq \emptyset$. Then, for any $p \in \Gamma$, $z \in D(A)$ and $r \in (0, \alpha)$, we have
$$\|T_r z - p\|^2 \leq \|z - p\|^2 - \|T_r z - z\|^2/2,$$
where $T_r = J^B_r(I - rA)$.

Proposition 2.1 (see, [5, 6]) Let $H$ be a real Hilbert space, let $F$ be as in Lemma 2.2 and let $T$ be a nonexpansive operator on $H$ such that $Fix(T) \neq \emptyset$. Then, for any bounded sequence $\{z^k\}$ in $H$ such that $\lim_{k \to \infty} \|Tz^k - z^k\| = 0$, we have
$$\limsup_{k \to \infty} (Fp_*, p_* - z^k) \leq 0,$$
(2.1)
where $p_*$ is the unique solution of (1.15) with $\Gamma$ replaced by $Fix(T)$.  

Nguyen T. Quynh Anh, Pham T. Thu Hoai
3. Main Results

First, we prove the following result.

**Theorem 3.1** Let \( H, B \) and \( A \) be as in Lemma 2.4 with \( \mathcal{D}(A) = H \) and let \( F \) be an \( \eta \)-strongly monotone and \( \tilde{\gamma} \)-strictly pseudocontractive operator on \( H \) such that \( \eta + \tilde{\gamma} > 1 \). Then, as \( k \to \infty \), the sequence \( \{z^k\} \), defined by

\[
z^{k+1} = T_kT_c(I - t_kF)z^k
\]

with conditions (r) and (t), converges strongly to \( p_\ast \), solving (1.15) with \( \Gamma = (A + B)^{-1}0 \).

**Proof.** First, we prove that \( \{z^k\} \) is bounded. We know that \( p \in \Gamma \) if and only if \( p \in \text{Fix}(T_r) \), that is defined in Lemma 2.4 for any \( r \in (0, \alpha) \). It means that \( \Gamma = \text{Fix}(T_r) \) for any \( r \in (0, \alpha) \). Thus, for any point \( p \in \Gamma \), from the nonexpansivity of \( T_k \) and \( T_c \) (see [3]), condition (r), (3.1) and Lemma 2.2, we have that

\[
\|z^{k+1} - p\| = \|T_kT_c(I - t_kF)z^k - T_kT_c p\|
\leq \|(I - t_kF)z^k - p\|
\leq (1 - t_k \tau)\|z^k - p\| + t_k\|Fp\|
\leq \max \{\|z^1 - p\|, \|Fp\|/\tau\},
\]

by mathematical induction. Therefore, \( \{z^k\} \) is bounded. So, is the sequence \( \{Fz^k\} \). Without any loss of generality, we assume that they are bounded by a positive constant \( M_1 \). Put \( y^k = (I - t_kF)z^k \). By using again the nonexpansivity of \( T_k \) and \( T_c \), Lemmas 2.4 and 2.2, we obtain the following inequalities,

\[
\|z^{k+1} - p\|^2 = \|T_kT_c y^k - T_k p\|^2 \leq \|T_c y^k - p\|^2
\leq \|y^k - p\|^2 - \|T_c y^k - y^k\|^2/2
\leq \|(I - t_kF)z^k - p\|^2 - \|T_c y^k - y^k\|^2/2
\leq (1 - t_k \tau)\|z^k - p\|^2 + 2t_k\langle Fp, p - z^k + t_kFz^k \rangle - \|T_c y^k - y^k\|^2/2
\leq \|z^k - p\|^2 + 2t_k\|Fp\|\|p\| + 2M_1 - \|T_c y^k - y^k\|^2/2.
\]

Thus,

\[
(\|T_c y^k - y^k\|^2/2) - 2t_k\|Fp\|\|p\| + 2M_1 \leq \|z^k - p\|^2 - \|z^{k+1} - p\|^2. \quad (3.2)
\]

Only two cases need to be discussed. When \( (\|T_c y^k - y^k\|^2/2) \leq 2t_k\|Fp\|\|p\| + 2M_1) \) for all \( k \geq 1 \), from condition (t), it follows that

\[
\lim_{k \to \infty} \|T_c y^k - y^k\|^2 = 0. \quad (3.3)
\]
When \((\|T_c y^k - y^k\|^2/2) > t_k\|Fp\||\|p\| + 2M_1\) from \(k = 1\) to \(M\), summing them side-by-side, we get that

\[
\sum_{k=1}^{M} \left[ \left( \|T_c y^k - y^k\|^2/2 \right) - 2t_k\|Fp\||(\|p\| + 2M_1) \right] \leq \|z^1 - p\|^2 - \|z^{M+1} - p\|^2 \leq \|z^1 - p\|^2.
\]

Then,

\[
\sum_{k=1}^{\infty} \left[ \left( \|T_c y^k - y^k\|^2/2 \right) - 2t_k\|Fp\||(\|p\| + 2M_1) \right] < +\infty.
\]

Consequently,

\[
\lim_{k \to \infty} \left[ \left( \|T_c y^k - y^k\|^2/2 \right) - 2t_k\|Fp\||(\|p\| + 2M_1) \right] = 0,
\]

that together with condition (t) implies (3.3). Next, from the definition of \(y^k\), we have that \(\|y^k - z^k\| = t_k\|Fz^k\| \leq t_kM_1 \to 0\) as \(k \to \infty\). Thus, \(\lim_{k \to \infty} \|T_c z^k - z^k\| = 0\). Consequently, \(\{z^k\} \) satisfies (2.1) with \(T = T_c\).

Now, we estimate the value \(\|z^{k+1} - p_s\|^2\) as follows.

\[
\|z^{k+1} - p_s\|^2 = \|T_k T_c (I - t_k F) z^k - T_k T_c p_s\|^2 \\
\leq \|(I - t_k F) z^k - p_s\|^2 \\
\leq (1 - t_k \tau) \|z^k - p_s\|^2 + 2t_k \langle Fp_s, p_s - z^k + t_k Fz^k \rangle \\
= (1 - b_k) \|x^k - p_s\|^2 + b_k c_k,
\]

where \(b_k = t_k \tau\) and \(c_k = (2/\tau) [\langle Fp_s, p_s - z^k \rangle + t_k \langle Fp_s, Fz^k \rangle]\).

Since \(\sum_{k=1}^{\infty} t_k = \infty\), \(\sum_{k=1}^{\infty} b_k = \infty\). So, from (3.4), (2.1), the condition (t) and Lemma 2.3, it follows that \(\lim_{k \to \infty} \|z^k - p_s\|^2 = 0\). This completes the proof. \(\square\)

**Remarks 1**

1.1. Since \(y^k = (I - t_k F) z^k\), from (3.1) with re-denoting \(t_k := t_{k+1}\), we get the method

\[
y^{k+1} = (I - t_k F) T_k y^k.
\]

Moreover, if \(t_k \to 0\) then \(\{z^k\}\) is convergent if and only if \(\{y^k\}\) is so and their limits coincide. Indeed, from the definition of \(y^k\), it follows that \(\|y^k - z^k\| \leq t_k\|Fz^k\|\). Therefore, when \(\{z^k\}\) is convergent, \(\{z^k\}\) is also bounded. Since \(t_k \to 0\) as \(k \to \infty\), from the last inequality and the convergence of \(\{z^k\}\) it follows the convergence of \(\{y^k\}\) and that their limits coincide. The case, when \(\{y^k\}\) converges, is similar.
It is well known (see, [6]) that the operator $F = I - f$, where $f = \pi I + (1 - \pi)u$ for a fixed number $\pi \in (0, 1)$ and a fixed point $u \in H$, is $\eta$-strongly monotone with $\eta = 1 - \pi$ and $\gamma$-strictly pseudocontractive with a fixed $\gamma \in (\pi, 1)$, and hence, $\eta + \gamma > 1$. Replacing $F$ in (3.1) and (3.5) by $I - f$ and denoting $t_k = (1 - \pi)t_k$, we get, respectively, the following methods,

\begin{align*}
  z_{k+1} &= T_k T_c(t_k' u + (1 - t_k') z_k), \\
  y_{k+1} &= t_k' u + (1 - t_k') T_k T_c y_k. \tag{3.6}
\end{align*}

Then, from Theorem 3.1, we obtain that the sequences $\{z^k\}$ and $\{y^k\}$, defined by (3.6), as $k \to \infty$, under conditions (t) and (r), converge strongly to a point $p_*$ in $\Gamma$, solving the variational inequality $\langle p_* - u, p_* - p \rangle \leq 0$ for all $p \in \Gamma$, i.e., $p_* = P_\Gamma u$. Beside, we have still that

$$
\|x^{k+1} - z^{k+1}\| = \|T_k T_c(I - t_k F)x^k + e^k - T_k T_c(I - t_k F)z^k\| \\
\leq (1 - t_k \tau) \|x^k - z^k\| + \|e^k\|,
$$

where $x^k$ and $z^k$ are defined, respectively, by (1.13) and (3.1). Thus, by Lemma 2.3, under conditions (t), (r) and (e), $\|x^k - z^k\| \to 0$ as $k \to \infty$, and hence, the sequence $\{x^k\}$ converges strongly to the point $p_*$. By the same argument as the above, we obtain that the sequence $\{x^k\}$ defined by either (1.9) or (1.10), under conditions (t), (r) and (e), converges strongly to the point $p_* = P_\Gamma u$, as $k \to \infty$.

1.2. Now, we consider the case, when $A$ maps a closed and convex subset $C$ of $H$ into $H$ and $D(A) \subseteq C$. Then, algorithms in (3.6) work well when $u$ and $x^1$ are chosen such that $u, x^1 \in C$.

1.3. $t_k = 1/\ln(1 + k)$ does not satisfy conditions in (r'). But, it can be used in our methods.

Further, we have the following result.

**Theorem 3.2** Let $H, B, A, \Gamma$ and $F$ be as in Theorem 3.1. Then, as $k \to \infty$, the sequence $\{z^k\}$, generated by (1.14) with conditions (r), (t) and (e), converges strongly to $p_*$, solving (1.15).

**Proof.** Obviously, for $\{z^k\}$, generated by

\begin{equation}
  z_{k+1} = \beta_k (I - t_k F) T_c z^k + (1 - \beta_k) T_k z^k, \tag{3.7}
\end{equation}

from (1.14), we get that

$$
\|x^{k+1} - z^{k+1}\| = \|\beta_k (I - t_k F) T_c x^k - (I - t_k F) T_c z^k + (1 - \beta_k) (T_k x^k - T_k z^k) + e^k\| \\
\leq \beta_k (1 - t_k \tau) \|x^k - z^k\| + (1 - \beta_k) \|x^k - z^k\| + \|e^k\| \\
= (1 - \beta_k t_k \tau) \|x^k - z^k\| + \|e^k\|.
$$
By Lemma 2.3 with condition $(t)$, $(\beta)$ and $(e)$, \( \|x^k - z^k\| \to 0 \) as \( k \to \infty \). So, it is sufficient to prove that \( \{z^k\} \), defined by (3.7), converges to the point \( p_* \). For this purpose, first, we prove that \( \{z^k\} \) is bounded. Since \( T_kp = p \) for any point \( p \in \Gamma \), from the nonexpansivity of \( T_k \), (3.7) and Lemma 2.2, we have that

\[
\|z^{k+1} - p\| \leq \|\beta_k((I - t_k F)T_c z^k - p) + (1 - \beta_k)(T_k z^k - p)\| \\
\leq \beta_k \|T_c z^k - p\| + (1 - \beta_k)\|T_k z^k - p\| \\
\leq (1 - \beta_k t_k \tau )\|z^k - p\| + \beta_k t_k \|Fp\| \\
\leq \max\{\|z^1 - p\|, \|Fp\|\}/\tau ,
\]

by mathematical induction. Therefore, \( \{z^k\} \) is bounded. So, are the sequences \( \{T_c z^k\} \) and \( \{F T_c z^k\} \). Without any loss of generality, we assume that they are bounded by a positive constant \( M_2 \). By using Lemmas 2.4 and 2.2, we obtain the following inequalities,

\[
||z^{k+1} - p||^2 \leq \beta_k^2 \|T_c z^k - p\|^2 + (1 - \beta_k)\|T_k z^k - p\|^2 \\
\leq \beta_k \left( (1 - t_k \tau )\|T_c z^k - p\|^2 + 2t_k \langle Fp, p - T_c z^k + t_k F T_c z^k \rangle \right) \\
\leq \left( 1 - \beta_k t_k \tau \right)\|z^k - p\|^2 + 2\beta_k t_k \langle Fp, p - T_c z^k + t_k F T_c z^k \rangle \\
- c_2 ||T_c z^k - z^k||^2 / 2
\]

where \( c_2 \) is a positive constant such that \( c_2 \leq \beta_k (1 - t_k \tau) \) for all \( k \geq 1 \). The existence of the constant is due to conditions \((\beta)\) and \((t)\). Thus, as in the proof of Theorem 3.1, we can obtain (3.3) with \( y^k = z^k \). So, \( \{z^k\} \) satisfies (2.1) with \( T = T_c \).

Now, from (3.8), we estimate the value \( \|z^{k+1} - p_*\|^2 \) as follows.

\[
\|z^{k+1} - p_*\|^2 = \|T_k T_c(I - t_k F)z^k - T_k T_c p_*\|^2 \\
\leq \|(I - t_k F)z^k - p_*\|^2 \\
\leq (1 - t_k \tau )\|z^k - p_*\|^2 + 2t_k \langle Fp_*, p_* - T_c z^k + t_k F T_c z^k \rangle \\
= (1 - b_k)\|z^k - p_*\|^2 + b_k c_k,
\]

where \( b_k = \beta_k t_k \tau \) and

\[
c_k = 2/\tau \left[ \langle Fp_*, p_* - z^k \rangle + \langle Fp_*, z^k - T_c z^k \rangle + t_k \langle Fp_*, F T_c z^k \rangle \right].
\]

Since \( \sum_{k=1}^\infty t_k = \infty \), \( \sum_{k=1}^\infty b_k = \infty \). So, from (3.3) with \( y^k = z^k \), (3.9) and Lemma 2.3, it follows that \( \lim_{k \to \infty} \|z^k - p_*\|^2 = 0 \). The proof is completed. \( \square \)
Remarks 2

2.1. Replacing $F$ in (1.14) by $I - f$, that is defined in remark 1.1, we obtain method (1.11) with $t_k' = \beta_k t_k(1 - \pi)$, $\beta_k' = \beta_k - t_k'$ and $\gamma_k' = 1 - \beta_k$.

2.2. Let $\tilde{\alpha} > 1$ and let $f$ be an $\tilde{\alpha}$-inverse strongly monotone operator on $H$. It is easily seen that $f$ is a contraction with constant $1/\tilde{\alpha} \in (0, 1)$, and hence, $F := I - f$ is an $\eta$-strongly monotone operator with $\eta = 1 - (1/\tilde{\alpha})$. Moreover,

$$\langle Fx - Fy, x - y \rangle = \|x - y\|^2 - (f(x) - f(y), j(x - y)) \\
\leq \|x - y\|^2 - \tilde{\alpha}\|f(x) - f(y)\|^2 \\
\leq \|x - y\|^2 - \gamma((I - F)x - (I - F)y)^2,$$

for any $\gamma \in (0, \tilde{\alpha}]$. Taking any fixed $\gamma \in (1/\tilde{\alpha}, \tilde{\alpha})$, we get that $F$ is a $\gamma$-strictly pseudocontractive operator with $\eta + \gamma > 1$. Next, by replacing $F$ by $I - f$ in (1.14), we obtain method (1.12) with the same $t_k'$, $\beta_k'$ and $\gamma_k'$.

2.3. Further, take $f = \pi I$ with a fixed number $\pi \in (0, 1)$. Then,

$$\langle f(x) - f(y), j(x - y) \rangle = \pi\|x - y\|^2 = (1/\pi)\|f(x) - f(y)\|^2,$$

and hence, $f$ is $\tilde{\alpha}$-inverse strongly monotone operator on $H$ with $\tilde{\alpha} = (1/\pi) > 1$. By the similar argument, we get a new method,

$$x^{k+1} = \beta_k(1 - t_k')T_rx^k + (1 - \beta_k)T_kx^k + e^k.$$

2.4. For a given $\alpha$-inverse strongly monotone operator $f$ on $H$, we can obtain an $\tilde{\alpha}$-inverse strongly monotone operator $\tilde{f}$ with $\tilde{\alpha} > 1$ by considering $\tilde{f} := \beta f$ with a positive real number $\beta < \alpha$. Indeed,

$$\langle \tilde{f}(x) - \tilde{f}(y), x - y \rangle = \langle \beta f(x) - \beta f(y), x - y \rangle \\
\geq \beta \alpha \|f(x) - f(y)\|^2 = \tilde{\alpha}\|\tilde{f}(x) - \tilde{f}(y)\|^2,$$

where $\tilde{\alpha} = \alpha/\beta > 1$.

4. Numerical experiments

We can apply our methods to the following variational inequality problem: find a point

$$p \in C \text{ such that } \langle Ap, p - x \rangle \leq 0 \text{ for all } x \in C,$$  \hspace{1cm} (4.1)

where $C$ is a closed convex subset in a Hilbert space $H$ and $A$ is an $\alpha$-inverse strongly monotone operator on $H$. We know that $p$ is a solution of (4.1) if and only if it is a zero for inclusion (1.1), where $B$ is the normal cone to $C$, defined by

$$N_Cx = \{w \in H : \langle w, v - x \rangle \leq 0, \forall v \in C \}.$$
Let \( \varphi \) be a proper lower semicontinuous convex function of \( H \) into \((-\infty, \infty]\). Then, the subdifferential \( \partial \varphi \) of \( \varphi \) is defined as follows:

\[
\partial \varphi(x) = \{ z \in H : \varphi(x) + \langle z, y - x \rangle \leq \varphi(y), y \in H \}
\]

for all \( x \in H \); see, for instance, [11]. We know that \( \partial \varphi \) is maximal monotone. Let \( \chi_C \) be the indicator function of \( C \), i.e.,

\[
\chi_C = \begin{cases} 
0, & x \in C, \\
\infty, & x \notin C.
\end{cases}
\]

Then, \( \chi_C \) is a proper semicontinuous convex function of \( H \) into \((-\infty, \infty]\) and then the subdifferential \( \partial \chi_C \) is a maximal monotone operator. Next, we can define the resolvent \( J^{\partial \chi_C}_{r_k} \) for \( r_k > 0 \), i.e., \( J^{\partial \chi_C}_{r_k} y = (I + r_k \partial \chi_C)^{-1} y \), for all \( y \in H \). We have (see, [30]) that \( x = J^{\partial \chi_C}_{r_k} y \iff x = P_C y \) for any \( y \in H \) and \( x \in C \).

For computation, we consider the example in [8], when

\[
C = \{ x \in \mathbb{E}^n : \sum_{j=1}^{n} (x_j - a_j)^2 \leq r^2 \},
\]

where \( a_j, r \in (-\infty; +\infty) \), for all \( 1 \leq j \leq n \).

Numerical computations are implemented with \( n = 3 \), \( a_1 = a_2 = a_3 = 2 \), \( r = 1 \) and \( Ax = \varphi'(x) \) where \( \varphi(x) = [(x_1 - 1.5)^2 + (x_2 - 1.3)^2]/2 \) for all \( x \in \mathbb{E}^3 \). Clearly, \( A \) is an 1-inverse strongly monotone operator on Euclidean space \( \mathbb{E}^3 \).

With taking \( u = (2.0; 1.0; 1.5) \), we get that \( p_* = P_C u = (1.5; 1.3; 1.5) \) is a solution of (4.1)-(4.2) where \( \Gamma = \{(1.5; 1.3; (-\infty, \infty))\} \cap C \) is the solution set of the stated problem. The computational results, using each method from (1.9), (1.11) and (1.12) with a starting point \( x^1 = (2.7; 2.5; 2.3) \), \( t'_k = 1/(k+1) \), \( \gamma'_k = 0.1 + 1/(k+1) \), \( \beta'_k = 1 - t'_k - \gamma'_k \), \( c = 0.5 \), \( r_k = 1/(k+1) \) and either \( e^k = 0 \) or \( e^k = (1.0; 1.0; 1.0)/k^2 \), are presented in numerical tables 1-6. Note that, using \( f = 0.9f \) in method (1.14), we have \( p_* \) is the point in \( \Gamma \) with minimal norm, where \( p_* = (1.5; 1.3; 2 - \sqrt{0.74}) \approx (1.5; 1.3; 1.13397674733) \). We do not calculate by method (1.10), because it is equivalent to (1.9). Analyzing the numerical results, we can conclude that the calculation by methods (1.9) and (1.11) is better than that by (1.12). Moreover, the calculation without errors, i.e., \( e^k = (0; 0; 0) \) for all \( k \geq 1 \), is also better than that with errors \( e^k = (1; 1; 1)/k^2 \). The numerical results above show that our methods work good and they are simpler than that in [8].

Further, for comparison, we give numerical results by methods (1.5) and (1.10) with the same \( t'_k \) and \( r_k = 0.1+1/(3k) \), satisfying conditions \( (r') \) and \( (r) \), where \( c = 0.4 \) and \( e^k = (0; 0; 0) \) in the tables 7 and 8, respectively. Numerical results computed by (1.10) and (1.8) with new \( r_k = 1/(k(k+1)) \), that has

</table>

properties ($r$) and ($\tilde{r}$), are given in tables 9 and 10, respectively. Tables of numerical results 7, 8, 9 and 10 show that method (1.8) gives the best result than the others. Perhaps, the quantity of information ($T_i$, $i = 1, 2, \cdots, k$), using at $k$th iteration step, for method (1.8) is more than that for the rest methods.

5. Conclusion

We have presented several iterative methods of Halpern or viscosity approximation types for finding a zero of a monotone inclusion in Hilbert spaces. We have showed that they are particular cases of our new two methods, designed for solving a monotone variational inequality problem over the set of zeros for the inclusion problem. Both these two methods are two combinations of the steepest-descent method with the forward-backward splitting one, strong convergence results of which have been proved under a new condition on resolvent parameter and weaker conditions on iterative parameter than that for other methods in literature. A numerical example was given for illustrating our methods and the comparisons of our new methods with others in literature have been done by computations with the same values of iterative parameters.
